The Maryland Department of Transportation State Highway Administration (MDOT SHA) strives to improve the lives of Maryland citizens and foster the economic vitality of the State by providing a safe, efficient and reliable highway system. The MDOT SHA team understands the direct impact that the movement of people and flow of goods has on our customers’ ability to connect to life’s opportunities. We face new challenges and shifting mobility trends each year, creating the need for progressive and cost-effective operations management, engineering, and context-sensitive design to manage our assets effectively and provide accessibility and mobility to our customers using all modes of transportation. This is where the Transportation Systems Management and Operations (TSMO) Program comes in—with a focus to effectively manage and operate existing facilities and systems and to maximize their full-service potential though Intelligent Transportation Systems (ITS). TSMO strategies leverage technology to optimize capacity that is limited by recurring and non-recurring congestion.

As MDOT SHA Administrator and former Chief Engineer for Operations, I am proud of the Coordinated Highway Action Response Team (CHART) Program’s success in traffic-incident management and reducing delays on our roadway network. In order to deliver the best customer experience possible, we are working every day to keep Maryland moving forward by incorporating new technologies to propel our transportation network into the future. Led by Acting Deputy Administrator of Operations in Hanover and Director of the Office of Transportation Mobility and Operations (OTMO), Joey Sagal, the TSMO Program aims to shape our next generation of Mobility and Operations. The TSMO Master Plan provides a goal-oriented, performance-based and outcome-driven approach for transportation investments in Maryland.

The TSMO Master Plan lays the foundation and provides steps on how to plan for and deploy TSMO solutions and strategies in the day-to-day planning, design, construction, maintenance, and operations activities associated with Maryland’s ITS. The TSMO Master Plan is a collaboration between the CHART, which provides monitoring and reporting of traffic conditions, emergency traffic patrol response, and active traffic management functions: the technical expertise of the Office of Traffic and Safety (DOTS), which is systematically upgrading traffic signals to adapt to changing traffic patterns and improve vehicular and pedestrian safety at our busiest intersections: and the local District Offices that are at the front lines of providing the customer experience to Maryland’s drivers and meeting our local stakeholders’ needs. Together, their many years of experience and unique areas of expertise will also help provide a cohesive approach to deploying projects and initiatives that will improve Maryland’s roadways.

Our System of Systems approach will allow Maryland to continue to be a leader in advancing technological innovation through our TSMO Program. I look forward to seeing great results as we continue to deploy the latest TSMO strategies and solutions using this collaborative and cohesive approach.

Tim Smith
Administrator
The Transportation System Management & Operations (TSMO) Master Plan presents a consistent vision for the Intelligent Transportation Systems (ITS) deployment in the State of Maryland. Unlike most visioning plans, TSMO uses a “System of Systems” approach in its evaluation, recommendations, and overall project development. This framework results in evaluation of transportation systems that integrate various disciplines and transportation modes, as opposed to single highway corridors. This approach allows TSMO practitioners to better understand the links between various transportation modes and highway corridors within each system, and ensure that recommendations do not simply shift the problems elsewhere.

The System of Systems also reflects the scalable nature of TSMO in its recommendations and deployment options. Transportation improvements can be deployed at a sub-system level, which may entail enabling certain ITS capabilities first, or advancing recommendations in certain corridors within a system, while keeping a consistent Master Plan vision for the entire system. The versatility of TSMO also allows for certain phases of project development to advance at different paces, for example advancing ITS deployment in certain systems, while minor system preservation type improvements are being designed, and larger capital improvements start their planning or preliminary engineering stages.

The TSMO Master Plan is organized in two parts. The first is the overall Master Plan, which identified seventeen transportation systems within the State and presents the evaluation methodology and overall recommendations. The second part is the TSMO Strategic Deployment, which focuses on the program development to advance the recommendations from the TSMO Master Plan and supporting projects and initiatives to maintain and expand current MDOT SHA capabilities.

1.0 MARYLAND STATEWIDE TSMO MASTER PLAN
Transportation System Management and Operations (TSMO) is a framework used by transportation agencies to identify and develop projects which maximize the service potential of transportation systems. TSMO can be differentiated from other development strategies through its emphasis on targeted operational improvements that do not require traditional capacity improvements (e.g., additional lanes, interchanges, routes, etc.). TSMO initiatives achieve this high level of efficacy by utilizing information technology to create intelligent transportation systems (ITS).

The ITS infrastructure promoted by the TSMO framework is composed of three basic parts: ITS devices, telecommunications networks, and decision support systems (see Figure 1). ITS devices allow agencies to collect information about the performance of transportation networks and alter operational conditions. For example, sensors which detect traffic speed help transportation agencies understand how efficiently traffic is moving through an area. When congestion is occurring, traffic engineers would use the data to determine if ramp meters (a type of ITS device used to moderate the entry of vehicles onto an access-controlled roadway) should be activated.

In order for ITS devices to be used effectively, there must be a telecommunications network which can transmit both the data collected and the response. With the advancement of technology, high-speed communication networks are becoming the golden standard. Fiber optic cables are becoming the golden standard which can transmit both the data collected and the response. The physical components of the decision support system include banks of displays, communication equipment (e.g., radios and telephones), and servers for hosting digital networks. The software components are programs designed to organize and analyze the incoming data so that traffic engineers can select the most appropriate response. The advancements in technology and increase in available real time data are creating a pathway for more automated systems that employ artificial intelligence to become part of future decision support systems.

The TSMO framework can also be distinguished from other development strategies by its heavy emphasis on integrating multiple scales of system analysis (e.g., local, corridor, and regional) and asset development (e.g., planning, design, construction, and maintenance). This emphasis is founded on the belief that transportation facilities function best when development focuses not just on individual facility characteristics (e.g., capacity) or agency actions (e.g., roadway widening), but also on broader systemic performance characteristics driven by the agency’s core mission. Maryland Department of Transportation (MDOT) refers to this development strategy as the System of Systems approach. Figure 2 illustrates how the System of Systems approach informs the TSMO Framework.

By embracing these strategies, as well as changes in institutional practice, transportation agencies across the nation have been able to use TSMO frameworks to not only improve user experiences, but also maximize the return on public investment. Thanks to a history of embracing technological innovation, all three parts of ITS infrastructure already exist within Maryland and support MDOT’s operations. Integrating the TSMO framework into MDOT’s program will carry this tradition forward and assure that Maryland has the infrastructure it needs to support the economy of the 21st century.

1.1 | WHAT IS TSMO?

1.2 | HOW DID THE TSMO PROGRAM BEGIN?
grant was an extension of a project designed to identify metrics DOTs could adopt to improve travel time reliability to address non-recurring sources of highway congestion (e.g., crashes, storms, and construction zones). Using these funds, MDOT conducted a series of workshops in 2014 and 2015 whose findings led to the re-organization of MDOT’s ITS activities and the preparation of the 2016 TSMO Strategic Plan. Based on its success developing and managing ITS networks, MDOT selected the Office of Transportation Mobility and Operations, which includes CHART, to be the office centrally responsible for overseeing the TSMO program and completing the Strategic Plan’s recommendations. At present, the TSMO program is focused on improving highway operations. As the program matures, its scope will strengthen the links to mass transit, pedestrian facilities, and inter-modal connections.

MDOT’s formal TSMO program began with the release of its TSMO Strategic Plan in August 2016. In this document, MDOT SHA translated the U.S. Department of Transportation’s (USDOT) national TSMO framework into goals and strategies that fit Maryland’s unique needs. Some of the Plan’s principal recommendations include the development of performance metrics for TSMO projects, increasing the amount of operational information available to the traveling public, and the creation of specialized TSMO teams throughout MDOT projects. In 2018, the Strategic Plan was updated to reflect changes in MDOT SHA, and the creation of specialized TSMO teams throughout MDOT SHA. In 2018, the Strategic Plan was updated to reflect changes in MDOT SHA’s project development process and recent technological advancements. The recommendations presented in the 2018 Strategic Plan are organized around four thematic goals:

- Business Processes & Collaboration;
- Systems & Technology;
- Data, Analysis & Performance Management;
- Customer Experience & Engagement.

Each goal is supported by objectives and strategies (see Figure 3). An objective is something MDOT SHA wants to achieve and strategies are actions that will help MDOT SHA achieve its objectives.

1.3 | WHY WAS THE TSMO MASTER PLAN CREATED AND WHAT IS ITS PURPOSE? The purpose of any Master Plan, be it for a residential community or a transportation system, is to make future investments more effective by articulating priorities and goals. In the case of the TSMO Master Plan, MDOT’s priority is to maximize the service potential of Maryland’s transportation systems. Like most transportation plans, the goals are projects or initiatives which the agency believes are worthy of further development.

The creation of a TSMO Master Plan is one of the three objectives supporting the Business Process & Collaboration Goal (see Objective 1.2 in Figure 3). The primary purpose of the TSMO Master Plan is to present, describe, and manage a collection of TSMO systems (see Strategy 1.2b in Figure 3). A TSMO system is comprised of one or more roadways owned and/or operated by MDOT whose traffic conditions could be improved through a coordinated set of TSMO projects. The publication of this information will support MDOT’s TSMO program by communicating performance metrics, illustrating the application of novel techniques, and serving as a starting point for further technical innovation.

The presentation and description of each TSMO system occurs on the fact sheets contained in Appendix A. Each fact sheet includes mapping of a system’s location and informational graphics which describe existing traffic conditions. To ensure technical accuracy and programmatic compatibility, each of the TSMO systems was prepared with input from MDOT’s disciplinary divisions (see Strategy 1.2a in Figure 3). The system fact sheets also identify the TSMO improvements which have the greatest potential to improve traffic conditions, the cost of completing the improvements, and the predicted user benefit. User benefit is the calculated economic value of the time and fuel that would have otherwise been lost due to congestion.

The predicted user benefit relative to the cost of completing the proposed improvements is one of the key criteria used to establish the business case for each of the TSMO projects (see Strategy 1.2c in Figure 3). When paired with the improvement type, this information also helps identify which of MDOT’s programs and funding streams are best suited to refine the recommended improvements into projects (see Strategy 1.2d in Figure 3).
1.4 WHAT INFORMATION IS USED TO DEVELOP THE TSMO MASTER PLAN’S RECOMMENDATIONS?

Since MDOT began conducting system performance analyses in the mid 1980’s, many of the references needed by the TSMO program already exist. The four most crucial (see Figure 4) of these are:

- MDOT SHA Mobility Report;
- Strategic Highway Safety Plan;
- Maryland Strategic Goods Movement Plan; and
- Transportation Asset Management Plan (TAMP).

In addition to serving as valuable planning references, the subject matter of these reports helps to illustrate the types of operational issues related to MDOT’s overall TSMO program. Outside of MDOT’s own data collection systems, one of the largest sources of information for the TSMO program is the University of Maryland’s Center for Advanced Transportation Technology Laboratory (CATT Lab). The CATT Lab’s mission is to support efforts to improve the operations of transportation systems through research, education, and the implementation of advanced technologies. One of the CATT Lab’s programs utilized by the TSMO program is the Regional Integrated Transportation Information System (RITIS). RITIS is an automated data sharing system that includes a wide range of performance statistics, including extensive records of traffic operations collected in real-time.

Successful development and execution of a TSMO program requires that transportation agencies not only gather detailed operational data, but also study the data in ways that will reveal the relationships between service failures. MDOT achieves this goal by organizing network analysis around four operational needs:

- Congestion;
- Reliability;
- Safety; and
- Freight.

Congestion

Congestion is the operational condition that occurs when the number of vehicles using a roadway is large enough that they can no longer safely travel at the facility’s design speed. In a 2004 report entitled Traffic Congestion and Reliability: Linking Solutions to Problems, FHWA identifies six causes of congestion:

- Travel Time Index or TTI;
- Level of Service (LOS);
- Economic cost of congestion on major corridors;
- The reliability of major corridors (i.e. Planning Time Index or PTI); and
- The distribution and reliability of freight traffic across the state.

These attributes are critical to the development of the TSMO program because they allow TSMO planners to identify where service failures exist and what might be causing them.

The annual MDOT SHA Mobility Report provides a detailed summary of the performance of the roadways operated by MDOT SHA. Some of the attributes documented in the Mobility Report include:

- Distribution of vehicle miles traveled by time and geographic region;
- Level of congestion experienced on major corridors (i.e. Travel Time Index or TTI);
- Economic cost of congestion on major corridors;
- Reliability of major corridors (i.e. Planning Time Index or PTI); and
- Distribution and reliability of freight traffic across the state.

These attributes are critical to the development of the TSMO program because they allow TSMO planners to identify where service failures exist and what might be causing them.

The Strategic Highway Safety Plan is a guidance document designed to help MDOT reduce the number of fatalities and serious injuries that occur on Maryland’s highways by 50% by 2030. The plan establishes performance targets for six emphasis areas: aggressive driving, distracted driving, impaired driving, highway infrastructure, and pedestrian and bicyclist safety. The Strategic Highway Safety Plan is an important resource for developing the TSMO program because it not only identifies areas where system upgrades are needed, but also describes relevant investment strategies.

The Maryland Strategic Goods Movement Plan is focused on the movement of freight through the state. The plan provides operational summaries for the major modes of freight movement (i.e. highway, rail, inland waterways, and aviation) and cargo types (i.e. agricultural, mining, construction, energy, wholesale, and manufacturing). These summaries not only cover existing statistics, but also the strategies MDOT is using to improve the reliability of freight movement. Each of these areas and strategies can be used by planners to identify the networks that need improvement and set goals for the TSMO program.

The MDOT Transportation Asset Management Plan (TAMP) is a report which lists all the roads and bridges MDOT owns that are part of the National Highway System (NHS). In the 2018 TAMP the statewide NHS inventory included approximately 9,037 lane miles of pavement and 1,932 bridges. TAMP is a valuable resource for planning the MDOT’s TSMO program. This information can help TSMO planners keep their records up to date and stage improvements to coincide with scheduled facility upgrades.
• Physical Bottlenecks are locations where traffic exceeds the maximum capacity capable of being handled by a given highway section. Capacity is determined by a number of factors: the number and width of lanes and shoulders; merge areas at interchanges; and roadway alignment (grades and curves).
• Traffic Incidents are events that disrupt the normal flow of traffic, usually by physical impedance in the travel lanes. Events such as vehicular crashes, breakdowns, and debris in travel lanes are the most common forms of incidents.
• Work Zones are construction activities on the roadway that result in physical changes to the highway environment. These changes may include a reduction in the number or width of travel lanes, lane “shifts,” lane diversions, reduction, or elimination of shoulders, and even temporary roadway closures.
• Weather are environmental conditions that can lead to changes in driver behavior that affect traffic flow.
• Poor Signal Timing are intermittent disruption of traffic flow by traffic control devices such as railroad grade crossings and poorly timed signals that contribute to congestion and travel time variability.
• Special Events are a special case of demand fluctuations whereby traffic flow in the vicinity of the event will be radically different from “typical” patterns. Special events occasionally cause “surges” in traffic demand that overwhelm the system.

There are two types of congestion: recurring and non-recurring. Congestion related to physical bottlenecks and traffic control devices is referred to as recurring because it tends to occur day-after-day, often at the same time and in the same location. All other causes of congestion are referred to as non-recurring. More than half of the total causes of congestion are non-recurring (see Figure 5).

In general, new construction is viewed as an appropriate response to recurring congestion. However, in the current economic environment, raising highway construction budgets is unlikely. Moreover, new construction does not address non-recurring congestion. By identifying and mapping the cause of the congestion, TSMO planners can trace the source of service failures to address both recurring and non-recurring congestion.

Reliability
Transportation agencies use the term reliability to refer to the consistency of travel times over the course of a given period (e.g. weekday mornings from September to May). FHWA uses several different statistics to assess reliability, including:

• The 50th percentile travel time (i.e. the time needed to complete a trip without congestion);
• The 95th percentile travel time (i.e. the time needed to complete a trip because of typical, recurring congestion);
• The 95th percentile travel time (i.e. the time needed to complete a trip because of incidental, non-recurring congestion); and
• Buffer index (i.e. the extra time needed to travel because of recurring or non-recurring congestion).

MDOT SHA’s TSMO program uses these statistics to calculate two key performance metrics: Travel Time Index (TTI) and Planning Time Index (PTI). Both metrics are ratios which describe the relationship between the travel time along a corridor under free flow conditions and travel time when congestion is causing delays. TTI is the ratio between these two conditions when the congestion is the result of recurring and non-recurring events. Extreme weather, crashes, and major league athletic events are good examples of incidents which generate non-recurring congestion. For both metrics, a large index value indicates a large disparity between how the corridor would ideally function and the user experience. By comparing PTI and TTI values, TSMO planners can assess the volatility of congestion and identify the relationships between contributing factors.

Safety
The preservation of public safety is the top performance criteria for every MDOT facility and initiative. The TSMO program embodies this mission by using the prevalence of crashes along a corridor as one of the principle means of identifying operational issues. By segregating crash records by type (e.g. rear-end, sideswipe, angle, etc.) and time of day, TSMO planners can highlight the areas where ITS measures (like the installation of smart signals) can not only protect the traveling public, but also reduce congestion caused by non-recurring events. Another important diagnostic metric is the number crashes per vehicle mile traveled. By adding this layer of context, TSMO planners can ensure that safety issues experienced on low-volume roadways aren’t overlooked.

Freight Movement
Out of the four categories of performance criteria used by the TSMO program, the movement of freight is arguably the most dynamic. This distinction comes from the inherently inter-modal nature of freight movement. Although the highway system conveys most of the freight moving through the State, Maryland’s diverse set of freight facilities means that operational issues that normally would be limited to a single facility type can branch out. Highway congestion on its own will affect the movement of heavy trucks through a region, but when it occurs near an important maritime facility, it can impact the movement of goods overseas.

The TSMO program addresses the complex nature of freight traffic by using the Maryland Strategic Goods Movement Plan to identify the most critical freight facilities and highlight the key inter-modal connections. Another key criterion is the distribution of specialized freight facilities. Overnight truck parking and weigh stations are both good examples of facilities which don’t directly influence the number of heavy trucks a highway can bear but have a strong influence on how safely and efficiently those trucks can complete their routes. Other important criteria used by TSMO planners include the occurrence of illegal truck parking and the economic losses generated because the movement of freight is delayed by congestion.

1.5 | HOW IS THE TSMO MASTER PLAN DIFFERENT FROM OTHER MDOT PLANNING EFFORTS?

What differentiates the TSMO Master Plan from other transportation planning efforts is the fluidity of its recommendations. Whereas traditional transportation plans describe future investments in very discrete terms (e.g. the construction of an interchange at a given intersection), the TSMO Master Plan describes a range of improvements that could be deployed to one or more related corridors. This flexibility is provided because the MDOT TSMO program is...
designed to be driven by performance-based metrics rather than a prescriptive vision of how the transportation network should look.

The TSMO Master Plan process (see Figure 6) is designed to fit between the Performance Based Planning and System Engineering (SE) processes. The data and analysis prepared for the Master Plan sets heavy emphasis on existing performance measures and operational needs at both the facility and network level based on broader understandings of regional goals. This process allows the TSMO Master Plan to serve as a link between documents expressing regional goals and the feasibility studies prepared in the SE process.

In addition to inviting potential solutions to compete for selection, the TSMO program’s emphasis on performance-based metrics requires planners to consider the effects on the larger network as opposed to focusing on a single location. It also allows MDOT’s design team to more easily respond to technological advancements. Unlike other elements of the transportation network, the capabilities of ITS assets are changing so rapidly that what appears to be cutting edge today may soon be outdated. In recognition of this, the TSMO Master Plan is presented as a living document that will be regularly updated. This process of revision will not only allow MDOT to respond to technology advancements, but also facilitate assessments of the TSMO program’s performance and track progress towards the objectives expressed in the TSMO Strategic Plan.

1.6 | HOW WERE THE TSMO MASTER PLAN’S RECOMMENDATIONS PREPARED?

The TSMO evaluation process culminates in recommended TSMO strategies (e.g. signal upgrades for congestion, camera deployment for incident response, transit signal priority for buses, hard shoulder running for capacity, etc.) and a proposed course of action to deliver the recommendations. The TSMO Master Plan’s recommendations were prepared through a three-step process (see Figure 7). These three steps are:

Step 1: Identification of Statewide Priorities

The preparation of the TSMO Master Plan’s recommendations begins with reviewing reference documents (from Section 1.4) and extracting data which describes TSMO key performance metrics (i.e. congestion, reliability, safety, and freight movement). Using these datasets, MDOT creates thematic maps which highlight areas where operation conditions could be improved. Corridors within these networks are then reviewed by teams of subject matter experts (e.g. regional planners, operational specialists, asset managers, roadway designers, district traffic, etc.) to add context to the gathered data and identify other regional or local needs and priorities. This first step helps identify the

---

**Identify Statewide Priority**

- Risks/Opportunities
- Phasing/Deployment

---

**TSMO MASTER PLAN**

---
gaps in the State’s transportation network and presents corridors and systems to be considered for screening.

**Step 2: Screen Corridors and Develop TSMO Systems**

The screening process begins with expanding the description of each corridor to include the condition of major assets, the presence of sensitive environmental resources, transit and multi-modal considerations, and unique operational characteristics. Assessments of asset condition help planners determine if TSMO upgrades could be integrated into upcoming maintenance efforts. Mapping of sensitive environmental resources helps TSMO planners identify constraints and mitigation requirements associated with potential construction activities.

Evaluation of this data, sometimes accompanied by operational studies, helps identify TSMO strategies tailored to fit the unique operational needs of each corridor. By combining the results of these processes, TSMO planners can select those corridors which fit the TSMO program best and assemble them into systems to be managed in a more coordinated fashion. These TSMO systems are comprised of multiple corridors (freeways and arterials) that share a common boundary and traffic operations, where operations of one corridor directly influence the other. These systems also take seasonal routes into consideration to support local tourism and multi-modal connections and systems that impact operations.

**Step 3: Perform System Analysis**

TSMO system analysis begins by focusing on a few general strategies to help communicate a vision based on transportation needs and existing technologies. This approach is used because MDOT’s catalog of TSMO strategies is constantly updated, and overly discrete recommendations are likely to hinder innovation and decrease the programs efficacy. Each strategy is evaluated from a system-wide perspective to ensure that improved operations along certain corridors do not shift the problem elsewhere and to focus on recommendations based on the end-to-end trip experience and user benefit. Multiple strategies are recommended for each TSMO system to address different needs within targeted locations in the transportation network.

Strategies that were evaluated but not recommended due to physical and/or operational constraints are documented in the individual corridor sheets used during screening for future reference. Recommended strategies are included in the TSMO System fact sheets included in Appendix A. The planning level costs and user benefits (see Figure 8) provide an order of magnitude of the potential infrastructure needs and return on investment to assist fiscal decision makers in prioritizing funding opportunities.

The three-step process results in the following:

- **Corridor Needs** (e.g. congestion, reliability, safety, freight)
- **TSMO Systems** (e.g. grouping of corridors and other transportation modes that influence each others’ operations)
- **Recommendations** (e.g. TSMO strategies organized by systems)

**TSMO Recommendation**

MDOT’s catalog of TSMO improvements covers a broad range of disciplinary specializations and construction requirements. As a result, the same development process is not ideal for all of the recommendations presented in the TSMO Master Plan. The last phase of the Master Planning process reacts to this diversity by identifying appropriate development processes and lead divisions. TSMO improvements involving the construction of hard running shoulders could require the renovation of ancillary highway systems (e.g. drainage systems) and are best handled by MDOT’s principal design offices and innovative contracting teams. Smaller scale system preservation projects or spot improvements may be led by the MDOT’s district offices. Implementation of smart traffic signals or ITS devices may be designed and led directly by MDOT’s asset managers. Lastly, TSMO systems with high environmental risk would be best studied by MDOT’s planning offices.

These recommendations do not prescribe specific improvements and locations, and will change as project development progresses. The TSMO Master Plan provides a framework to advance these recommendations as part of scalable systems and sub-systems based on identified operational needs rather than specific treatments. Strategies identified in the Master Plan will be re-evaluat-ed in planning, design and as part of the SE process where they may be modified, discarded, and new strategies may be added to the sub-systems based on updated information, refined analyses, and potentially new technologies and TSMO strategies.
1.7 | WHAT’S IN THE TSMO MASTER PLAN?

The TSMO Master Plan presents a vision of a Statewide Multi-Scalar System of Systems (see Figure 10). Each system is composed of one or more recommended project, grouped into sub-systems. The term multi-scalar reflects the nature of TSMO projects that not all recommended improvements must be delivered at once. Smaller sub-systems may be deployed enabling certain TSMO strategies and still strive for a larger vision for the TSMO System. For example, traffic cameras and detectors may be deployed initially to increase situational awareness on freeways and arterials improving overall incident response times. Subsequent sub-systems leverage the initial deployment to provide traveler information signs to communicate traffic conditions to drivers or to expand online services to provide information before they initiate their travels. Later deployments may include ramp meters or queue warnings that utilize the cameras, detectors, and message signs deployed in previous sub-systems.

The plan presents seventeen TSMO Systems that make up Maryland’s most significant corridors and presents analyses and recommendations for TSMO treatments within each sub-system (see Figure 12). The plan also includes fact sheets in Appendix A summarizing the traffic operations, identified TSMO strategies, costs, user benefits, and current efforts for every TSMO System. Sub-systems are categorized in three tiers (see Figure 10) that reflect priorities and ease of deployment as described next:

- Tier 1 sub-systems are higher priority with lower construction costs and impacts that are likely to advance be deployed within one to three years.
- Tier 2 sub-systems leverage infrastructure and technologies deployed from Tier 1 projects and involve more complex construction and technologies and are planned to be advanced within three to five years.
- Tier 3 sub-systems require civil improvements (i.e. roadway widening/reconstruction, improvement to structures such as bridges, stormwater management, and other ancillary components) and additional Federal and State approvals and will require over five years to plan, design, and deploy.

1.8 | WHAT HAPPENS NEXT?

After the Master Plan: Linking Planning and Design

After the planning process is complete, teams of subject matter experts are formed to scrutinize the Master Plan Systems’ recommendations and develop a formal Concept of Operations (ConOps). These teams include a wide range of perspectives, including: ITS specialists, traffic engineers, planners, asset managers, emergency responders, local partner agencies, and academic researchers. These teams use the information collected during the screening process to explore project implementation, operational performance, and revisit the cost-benefit evaluations. Together, these reassessments provide the information needed to select, modify, or add TSMO strategies. The ConOps teams then create a menu of smaller projects by grouping proposed TSMO strategies based on their operational characteristics. This multi-scalar system approach provides flexibility in funding and delivering sub-system improvement (e.g. breakout projects) consistent with the Master Plan, as depicted in Figure 11.

Tracking

The next part of the Master Plan, the TSMO Strategic Deployment, tracks and prioritizes the recommendations from the Statewide System of Systems. The Master Plan will be regularly updated to reflect changes in technology, land use, and changes in the transportation network within the TSMO systems; to track the evolution of the its recommendations into transportation improvement projects; and to update the statewide vision as sub-systems are deployed. Since the initial TSMO Strategic Plan, MDOT SHA has advanced various activities that support the TSMO Master Plan. These are:

- I-270 ICM (System 12)
- I-695 TSMO Design Build
- I-270/ I-495 Managed Lanes Study
- I-270 Active Traffic Management Study (System 2)
- System 1 Concept of Operations
- Baltimore-Washington Concept of Operations (System 13)
- US 1 Smart Traffic Signal Corridor (Systems 2&13)

2.0 TSMO STRATEGIC DEPLOYMENT
2.1 WHAT IS A STRATEGIC DEPLOYMENT PLAN?

The growth of MDOT’s TSMO program will require CHART to take new roles and capabilities beyond the conventional incident management and highway operations (see Figure 13). These new responsibilities will require CHART to employ collection of ITS solutions. The Strategic Deployment Plan identifies the long-range costs to sustain current CHART operations, and to expand its capabilities to support MDOT’s TSMO Strategic and Master Plans.

The Strategic Deployment Plan achieves these goals by identifying the operational needs and goals for CHART, planning opportunities for MDOT, and key performance measures. As a companion and extension of the TSMO Master Plan, the Strategic Deployment Plan also acts as a catalyst for stakeholder communication and collaboration. These activities will, in turn, help articulate a consistent statewide vision and deployment priorities. For example, the Strategic Deployment Plan can be used to identify projects which should be added to future MDOT’s CTP and CHART’s programming process.

In addition to describing how CHART can adapt to support the TSMO Master Plan, the Strategic Deployment Plan also presents actions associated with MDOT’s broader TSMO program. These include personnel training and equipment, upgrades and replacement of existing assets including buildings, software and system costs, telecommunication connections, and other ITS deployments outside the geographic boundaries of the TSMO Systems identified in the Master Plan. The Strategic Deployment Plan also accounts for the operations and maintenance costs as well as recurring costs associated with ITS deployment based on a life-cycle planning cost.
The Strategic Deployment Plan provides a means for:

- Identifying new projects to be added to future MDOT CTPs and initiate CHART’s project planning and programming process;
- Portraying the possibilities of future program operations to all stakeholders and decision-makers;
- Providing a consolidated CHART vision for future deployments and operations consistent with the TSMO Master Plan.

ITS projects and ancillary support projects and initiatives are presented as a “menu” of options for periodic deployment with associated operations and maintenance costs that span a planning time line of twenty years. The intended effect of these projects is to improve safety, mobility, reliability, increase traveler situation awareness, and develop the future capabilities identified in the TSMO Master Plan. The projects are categorized into six major planning areas (see Figure 14):

1. Traffic and Roadway Monitoring
2. Traffic Incident Management
3. Multi-Modal Traveler Information
4. Active Traffic Management
5. Systems Integration and Communication
6. Emergency Operations

These planning areas, also referred to as CHART’s Core Elements, were modified to include the expanded TSMO roles and capabilities. The integration of TSMO expands Core Element 3 to include “Multi-Modal” traveler information to encompass connection and coordination with other transportation modes; Core Element 4 to include “Active” traffic management to account for active traffic management capabilities; and Core Element 5 to include “Systems Integration” to highlight the importance of the decision support software and system integration required to deliver the TSMO Master Plan. The Core Elements are further described below:

Traffic and Roadway Monitoring

Actions within this element are designed to improve highway safety and efficiency by augmenting CHART’s ability to rapidly respond to hazardous highway conditions through enhanced traffic and roadway monitoring, including the use of new technology and additional device deployment. The amount of probe data available for traffic monitoring continues to increase, expanding the opportunities to utilize crowd source data and big data applications.

Traffic Incident Management

Actions within this element are designed to quickly and efficiently restore normal traffic flow after an incident by enhancing CHART’s incident management program through training of personnel, technology solutions, and teamwork both internally and with other agencies.

Multi-Modal Traveler Information

Actions within this element are designed to provide timely and reliable mobility information to the traveling public both prior to travel and en route using roadside devices, electronic media, and public-private partnerships with information providers.

Active Traffic Management

Actions within this element are designed to reduce congestion on highways by employing traffic management strategies to control vehicular movements, increase highway efficiency, and encourage travelers to choose alternative modes of travel. Integrated Corridor Management leverages real-time data and analysis and decision support systems to optimize vehicular operations.

Systems Integration and Communications

Actions within this element are designed to expand the CHART Advanced Transportation Management System (ATMS; the operating system) and network to support inter-agency and inter-modal coordination, connectivity and sharing of transportation management information. The volume of big data continues to increase requiring the overall system to be nimble to big data fusion from multiple sources, interoperability and compatibility of data and capabilities, edge computing coordination with centralized decision support systems, and planning for future CAV data needs.

Emergency Operations

Actions within this element are designed to establish a secure, resilient, and safe transportation system by deploying emergency response equipment and establishing coordinated preparedness and response plans for large-scale natural and man-made disasters, including adverse weather responsive management operations, terrorist activities and evacuations.
### 2.2 | HOW IS THE STRATEGIC DEPLOYMENT PLAN DEVELOPED?

The development of the Strategic Deployment Plan began with a review of the recommendation of TSMO Master Plan applicable to CHART’s responsibilities. The selected recommendations were then used to initiate three planning exercises:

- Begin the ITS Project Development Process;
- Develop the Scope of Work; and to
- Initiate ITS Project Programming Process to advance projects.

#### ITS Project Development Process

This is a cyclical process and follows a high-level SE process (see Figure 15). This process is overseen and directed by the CHART Board of Directors and the TSMO Executive Committee, and begins with identifying ITS Project Needs, which is directly informed by the findings and recommendations from the TSMO Master Plan. The process continues with the following steps:

- **Planning/Stakeholder Input:** Gathers stakeholder inputs to explore project concepts and feasibility through feasibility studies and ConOps documents;
- **Design:** Uses the ConOps to develop requirements and detailed design;
- **Construction:** Implements all pieces of the project such as installation of field devices and development of software and hardware;
- **Acceptance Testing:** Tests and validates individual components of the system for functionality according to requirements;
- **Network Integration:** Integrates the system into the CHART network for operations to begin;
- **Operations and Maintenance:** Operates the system as part of daily operations and subsequently performs routine and emergency maintenance throughout the life of the system.

#### Scope of Work

The Scope of Work is defined on the information collected from the ITS Project Need and the Planning/ Stakeholder Input step. There are three primary considerations in developing scopes of projects in this plan: deployment priority, deployment constraint, and state of technology. (See Figure 16)

Deployment priorities: Statewide systems, sub-systems, and corridor priorities are identified in the TSMO Master Plan, which identifies preliminary needs, strategies, costs, risks, and user benefits. The Strategic Deployment Plan categorizes the ITS and supporting infrastructure from the TSMO Master Plan and provides a deployment sequence to achieve desired operational capabilities.

#### ITS Project Programming Process

Once projects are prioritized and the scope of work has been developed, the ITS projects must obtain funding to advance into design and subsequent phases of the ITS Project Development Process. This process is depicted in Figure 17 and described below:

- **A** TSMO Master Plan: ITS deployment projects must be included in the Statewide TSMO Master Plan to ensure a consistent vision for future deployment and operations. The Master Plan provides information regarding the needs, such as traffic, incidents, crashes, asset conditions, environmental constraints, and summaries of past studies and planning initiatives.

- **B** Other Inputs: stakeholder input is integral to the development of the TSMO Master Plan, but there are times that priorities arise outside of the time frame when the TSMO Master Plan is developed and updated. Projects outside of the TSMO Master Plan must move to step C for project exploration and identification.

- **C** Project Exploration and Identification: gathering information from the previously defined planning documents and initiatives to determine the project needs, such as traffic, incidents, crashes, asset condition overview, and environmental resources. Projects in the TSMO Master Plan already have this information, therefore this step is only required for unexpected projects that arise from step B. Information developed for unexpected projects are included in the
The TSMO Master Plan to ensure consistency with other Statewide initiatives and recommendations.

**High-Level Project Summary:** Develop to include the project in the MDOT Consolidated Transportation Program (CTP) to begin the programming process. For most projects, the information required is identified in the TSMO Master Plan and include:

- Project Title
- Preliminary cost estimate
- Rough scope definition
- Projected implementation schedule
- High-level benefits and needs addressed

**Projects for MDOT CTP:** Develop detailed listings and descriptions of capital projects that are proposed for construction, development and evaluation during the next six years. CHART updates its projects and budgets every year for submittal to the MDOT CTP.

**Detailed Project Descriptions and ITS Architectures / Systems Engineering (SE) Analysis:** Required to be carried out prior to a project going through the Preliminary Engineering Phase (if applicable), and eventually entered into the Federal and MDOT Project Setup Phase. Detailed project description expands on the high-level summary and typically includes:

- Brief project description and/or background
- Refined cost estimate
- Detailed scope (e.g., system functionality, location, number of devices, etc.)
- Project tasks and/or milestones
- Project schedule
- Refined high-level benefits and needs addressed
- Project funding source

The project-level ITS architecture and CE compliance documentation is carried out to fulfill the FHWA rule on ITS Architecture and Standards, which implements section 5206(e) of the Transportation Equity Act for the 21st Century (TEA-21). This final rule/policy requires that ITS projects funded by the Highway Trust Fund conform to the National ITS Architecture. Part of this process includes a project-level architecture, as well as a SE analysis.

**Preliminary Engineering (if needed):** Define all details about the deployment prior to beginning the final project design. Not all CHART projects require preliminary engineering services such as projects that are solely equipment procurement.

**Federal & MDOT Project Setup:** Project is documented in the Federal and/or MDOT project tracking systems, which records budget, payments, scheduling, etc. The USDOT/FHWA project setup utilizes project information from (1) Project-level ITS architecture and (2) Systems Engineering analysis documents.

**Design Request:** Follows the Federal and MDOT Project Setup and is the last phase within the CHART Project Planning and Programming Process. Once the project is setup in the USDOT/FHWA and/or MDOT project system, it can then move forward with design and deployment.

### 2.3 WHAT IS INCLUDED IN THE COSTS?

Projects are presented as profiles (see Appendix B) that provide a practicable understanding of what CHART needs to build, develop, integrate, and initiate to achieve the plan’s objectives. The projects and capital costs focus on the following categories:

- **Field and Infrastructure Deployment** – includes activities such as device site selection, site preparation, construction of supporting infrastructure, device purchase, installation, etc.
- **Integration and Communications** – includes activities such as provisioning the required communications to each device site, configuring and installing the networking/system equipment, test/validate, etc.
- **Software Development** – includes the modification and module development for the central CHART system software, development of device drivers and communications protocol modules for new technology device that must be integrated into the central CHART system software.

The notion behind this is to facilitate identification of projects by the appropriate parties to obtain input for planning and programming to advance the project.

### Cost Estimates

Cost estimates were developed for the ITS projects outside the TSMO Master Plan’s Systems, initiatives required to support CHART’s growing responsibilities, and ancillary efforts. Construction costs were developed using MDOT SHA’s Construction Cost Manual and other historically available data. These are intended to provide a “ballpark” funding estimate required for CHART to build on its existing operations. All estimated costs are in current dollars and are for planning purposes only.
Software Development Considerations

CHART is MDOT SHA’s statewide customized ATMS supporting freeway incident and mobility management functions. As statewide operations evolve to support various TSMO strategies across all roadway networks the need to expand the CHART system capabilities will need to be evaluated. CHART was developed as a custom software platform since at the time of its inception, no suitable solution existed that met MDOT SHA’s operational needs. As additional functional capabilities are planned, a Systems Architecture/SE analysis will help determine the most effective roadmap moving forward. There are essentially three different methods for expanding the functionality of the CHART system capability: custom developed, commercial off-the-shelf (COTS), and semi-custom developed. These approaches may be mixed and matched by project specific opportunity or capability feature enhancement. The trade-offs between the different methods include deployment time, overall cost, traffic needs, reliability/accuracy, compatibility of future deployments, and ownership risk. General considerations are reflected in Figure 19.

Operations and Maintenance

A successful ITS program requires a strong commitment to efficiently operating and maintaining field devices, system components, communications network, and software. For the purposes of this Plan, operations and maintenance (O&M) costs have been determined as an estimated percentage of capital costs. O&M cost estimates for Field and Infrastructure Deployments, Integration and Communications, and Software Development are 15%, 15%, and 4.6% of capital costs respectively.

The O&M for Field and Infrastructure, and Integration and Communication projects account for the following associated costs:

- Management staff hours – full-time labor to manage day-to-day program activities/initiatives, contracts, in-house planning and technical studies, operational/maintenance staff, public outreach, training, coordination with other agencies, and general program decision-making.
- Operational staff hours – full/part-time and on-call labor to control, configure, provide security, administer, and troubleshoot systems/software/communications electronics and hardware; undergo training; provide patrolling and incident management services along highways; perform other administrative program/office functions.
- Maintenance staff hours – full/part-time MDOT SHA labor or contracted labor to troubleshoot, repair, run diagnostics on, and generally perform upkeep on CHART field devices and system components.
- Operational expenses – costs related to day-to-day running of facilities and systems, including building use costs, monthly phone and power, and leased communication lines.
- Maintenance expenses/equipment – costs to supply spare parts, vehicles, equipment, and tools needed to repair CHART field devices and system components.

O&M costs for Software Development projects are defined as a percentage of the original development to provide intermittent “fixes” to initial software. This estimate does not include true software “enhancements”, which would require significant programming to add software functionality, and are thus considered a separate standalone project.

Based on information collected throughout the ITS arena, a system O&M cost of 15% of CHART’s capital expenditures is considered appropriate. While
this figure could be on the high side, it enables decision-makers to know with greater certainty that the O&M cost estimates are under-represented, as is often the case. A 4.6% software cost estimate is based on documented software support estimates for initial implementation adjustments (FHWA ITS Joint Program Office – The Road to Successful ITS Software Acquisition, Volume II).

The plan assumes deployment of the devices in phases based on past experience and current deployment capabilities. O&M costs are accounted for a 20 year life cycle timespan and are averaged throughout the phases a project. These deployment costs and phases are intended to assist capital programing purposes and require traffic and system engineering studies to advance in project development.

2.4 | WHAT IS IN THE 2020 PLAN?

The 2020 Strategic Deployment Plan includes over 200 projects or initiatives, with a total estimated cost for planning/ preliminary engineering and construction of approximately $1.2 billion. The Strategic Deployment Plan includes improvements proposed by the TSMO Master Plan organized by TSMO System, and broken down by sub-systems organized by corridors or proposed TSMO strategy. As mentioned before, the plan also includes costs for supporting projects and initiatives for CHART’s operations. The costs included in the plan are associated with CHART’s Core Elements, as shown in Figure 20.

Structure of the Strategic Deployment Plan

The projects are organized into four major groups:

- TSMO Master Plan Systems and Sub-Systems
- Areawide ITS Deployment (outside TSMO Master Plan System boundaries)
- Personnel, Equipment, and Infrastructure
- Software Development and Systems Integration

TSMO Master Plan Systems and Sub-Systems

This group contains the projects which constitute the seventeen systems recommended in the TSMO Master Plan (see Appendix A). Sub-systems are organized based on four types of strategy being recommended:

1. ITS Deployment: primarily in the form of video cameras, traffic detectors, roadside units for CAV, virtual weigh stations, weather stations, dynamic message signs for traveler information, etc. These strategies focus on enhancing highway monitoring and traffic data collection, improving traveler information (including en route and for multi-modal connections), and improving incident response time by expanding situational awareness at traffic operations centers.

2. Traffic Signals: upgrade and integrate existing traffic signals to enable freeway/ arterial congestion management and active traffic management along the arterials. Upgrades also include video cameras for safety and incident detection, roadside units to CAV, and transit signal priorities for select arterials with existing or planned transit operations.

3. Telecommunications: identifies fiber optics, cellular, and radio communication needs to support the TSMO Master Plan. Recommendations in this plan leverage the findings from the Statewide Telecommunications Plan, currently under development.

4. Active Traffic Management: include combination of ITS and roadway civil improvements to enable active traffic strategies such as hard shoulder running or ramp metering. The deployment time frame for these projects are longer term than the previous categories because they require more Federal and State approvals as they involve roadway construction/ reconstruction.

Areawide ITS Deployment

This group contains projects which deploy ITS assets beyond the geographic boundaries of the seventeen TSMO Systems (see Appendix B). Projects in this category are just as important as the TSMO systems, but are simply not geographically connected. Examples in this category include replacement of existing devices, safety warnings at rural crossings, ITS warnings for railroad crossings, weather stations at specific bridges, or deployment of mobile devices for incident response, inclement weather, or for construction sites.

Software Development and Systems Integration

The existing ATMS employed by CHART requires new software and system integration (see Appendix B) to enable freeway/ arterial coordination, integrated corridor management and active traffic management strategies recommended in the TSMO Master Plan.

2.5 | WHAT IS IN THE APPENDIX?

Appendix A presents the fact sheets for the TSMO Master Plan Systems. This includes three fact sheets per system summarizing: overall system needs in terms of congestion and safety; recommended shorter-term ITS related projects; and recommended longer-term improvements requiring roadway civil work.

Appendix B presents areawide ITS projects, personnel/ equipment/ infrastructure projects and initiatives, and software and system integration projects.

Both appendices present planning-level cost estimates for planning and programming purposes. Projects costs and scope will be refined as funding becomes available and TSMO Projects advance in project development.
TSMO MASTER PLAN

TSMO SYSTEM # 1

BACKGROUND: TSMO System # 1 improves operations for major traffic movements along I-70 and US 29 heading to/from Baltimore, Columbia, and Fort Meade. The system has major bottlenecks around I-70/US 29 and I-70/Mariottsville Road during both peak periods. I-70 is designated as a Maryland Freight Route and is part of the National Freight Network. US 40 and US 29 have been identified as potential transit corridors.

SAFETY OVERVIEW: The highest concentrations of crashes are along I-70 around the US 29 interchange and approaching the I-695 interchange. Crash data shows that the highest number of crashes occur during the AM or PM peak and the most common crash type is rear ends. In 2018, there were 686 crashes reported within TSMO System # 1, with three fatalities and 230 injuries.

CRASH DENSITY

System 1 Hourly Crashes

Crash Types:
- Head On (3)
- Intersection (46)
- Rear End (313)
- Side Swipe (67)
- Angle (37)
- Single Vehicle (179)
- Other (44)

**SUB-SYSTEM DEPLOYMENT:**

- **System 1.1**  
  - **Tier 1**  
    - I-70 ITS Deployment  
    - Deployment of CCTV, DMS, traffic detectors, and RSUs along I-70 between MD 52 and I-695.  
    - PI: $0.8 M  
    - CO: $4.0 M  
    - Recurring Cost: $516.6 K  
    - Annual O&M: $0.6 M

- **System 1.2**  
  - **Tier 1**  
    - US 29 ITS Deployment  
    - Deployment of CCTV, traffic detectors, and RSUs along US 29 between I-70 and MD 140.  
    - PI: $0.8 M  
    - CO: $0.8 M  
    - Recurring Cost: $14.8 K  
    - Annual O&M: $0.8 M

- **System 1.3**  
  - **Tier 1**  
    - US 40 ITS Deployment  
    - Deployment of CCTV and traffic detectors along US 40 between I-70 and I-695.  
    - PI: $0.8 M  
    - CO: $0.8 M  
    - Recurring Cost: $18.6 K  
    - Annual O&M: $0.8 M

- **System 1.4**  
  - **Tier 1**  
    - I-70 Ramp Meter/Queue Warning System  
    - Deploy detectors, cameras, and DMS along I-70 between MD 52 and US 29 to implement queue warning/dynamic speed advisory systems and ramp metering.  
    - PI: $1.5 M  
    - CO: $10.3 M  
    - Recurring Cost: $106.3 K  
    - Annual O&M: $1.5 M

- **System 1.5**  
  - **Tier 1**  
    - US 40 Traffic Signal Upgrade  
    - Upgrade existing traffic signals along US 40 between I-70 and I-695 to be fully-actuated, equipped with S-Cabinets, have Video Detection, have CCTV Equipment, ATMS enabled, and have TIP.  
    - PI: $0.4 M  
    - CO: $5.2 M  
    - Recurring Cost: $12.2 K  
    - Annual O&M: $0.4 M

- **System 1.6**  
  - **Tier 1**  
    - MD 32 Traffic Signal Upgrade  
    - Upgrade existing traffic signals along MD 32 between MD 144 and MD 59 to be equipped with S-Cabinets, have Video Detection, have CCTV Equipment, ATMS enabled.  
    - PI: $0.8 M  
    - CO: $0.9 M  
    - Recurring Cost: $1.4 K  
    - Annual O&M: $0.8 M

- **System 1.7**  
  - **Tier 1**  
    - MD 144 Traffic Signal Upgrade  
    - Upgrade existing traffic signals along MD 144 between MD 32 and US 29 to be equipped with S-Cabinets, have Video Detection, have CCTV Equipment, ATMS enabled.  
    - PI: $0.8 M  
    - CO: $0.8 M  
    - Recurring Cost: $4.0 M  
    - Annual O&M: $0.8 M

- **System 1.8**  
  - **Tier 1**  
    - MArrieville Traffic Signal Upgrade  
    - Upgrade existing traffic signals along Marrrieville Road between MD 144 and MD 59 to be equipped with S-Cabinets, have Video Detection, have CCTV Equipment, ATMS enabled.  
    - PI: $0.8 M  
    - CO: $0.8 M  
    - Recurring Cost: $2.2 K  
    - Annual O&M: $0.8 M

TSMO MASTER PLAN

TSMO SYSTEM # 2

The TSMO System # 2 improves operations along I-95, MD 100, and MD 32 that provide access to BWI, Anne Arundel Mall, and Fort Meade. I-95, MD 32, and MD 100 are part of the National Highway Freight Network. MD 175 and MD 100 are critical urban freight corridors. MD 175, US 1, MD 32, and MD 100 have been identified as potential transit corridors.

BACKGROUND:

CRASH DENSITY

The highest concentrations of crashes are along I-95 just north and south of MD 175. MD 175 and MD 100 also have high concentrations of crashes around MD 295. Crash data shows that the highest number of crashes occur during the AM or PM peak and the most common crash type is rear ends. In 2018, there were 932 crashes reported within TSMO System # 2, with three fatalities and 322 injuries.

SAFETY OVERVIEW:

I-95 HOURLY TTI

I-95 HOURLY PTI

SYSTEM 2 HOURLY CRASHES

SYSTEM 2 CRASH TYPE

- Head On (8)
- Intersection (93)
- Rear End (71)
- Side Swipe (46)
- Angle (8)
- Single Vehicle (27)
- Other (49)

Annual O&M costs: $5.5 M

### SUB-SYSTEM DEPLOYMENT:

1. **System 2.4.1 (B/C: 10)**
   - **Tier 2:** I-95 Hard Shoulder Running (ITS)
   - **Description:** Deployment of dynamic lane controls, fixed cameras, CCTV, Communication and ITS equipment, and fiber connection for outside hard shoulder running along I-95 at key locations.
   - **Annual:** $3.3 M
   - **CO:** $22.2 M

2. **System 2.4.2 (B/C: 20)**
   - **Tier 2:** I-95 Hard Shoulder Running (Roadway)
   - **Description:** Civil improvements for outside hard shoulder running along I-95 at key locations.
   - **Annual:** $3.1 M
   - **CO:** $20.6 M

3. **System 2.4.3 (B/C: 23)**
   - **Tier 3:** MD 100 Hard Shoulder Running (ITS)
   - **Description:** Deployment of dynamic lane controls, fixed cameras, CCTV, Communication and ITS equipment, and fiber connection for outside hard shoulder running along MD 100 at key locations.
   - **Annual:** $3.1 M
   - **CO:** $20.6 M

4. **System 2.4.4 (B/C: 23)**
   - **Tier 3:** MD 100 Hard Shoulder Running (Roadway)
   - **Description:** Civil improvements for outside hard shoulder running along MD 100 at key locations.
   - **Annual:** $3.1 M
   - **CO:** $20.6 M

5. **System 2.4.5 (B/C: 23)**
   - **Tier 3:** MD 32 Hard Shoulder Running (ITS)
   - **Description:** Deployment of dynamic lane controls, fixed cameras, CCTV, Communication and ITS equipment, and fiber connection for outside hard shoulder running along MD 32 at key locations.
   - **Annual:** $3.1 M
   - **CO:** $20.6 M

6. **System 2.4.6 (B/C: 23)**
   - **Tier 3:** MD 32 Hard Shoulder Running (Roadway)
   - **Description:** Civil improvements for outside hard shoulder running along MD 32 at key locations.
   - **Annual:** $3.0 M
   - **CO:** $20.3 M

### PROGRESS STATUS:

- Baltimore-Washington Concept of Operations (completed)
- I-95 Active Traffic Management (in Design)
- US 1 Smart Traffic Signals (in Development)
BACKGROUND: TSMO System # 3 improves operations around Fort Meade and BWI and connects the region to Washington DC and the Eastern Shore via US 50. The System connects to US 301 providing alternative north-south route to MD 295. I-97, US 50, and MD 3 are designated as Maryland Freight Routes; I-97 and US 50 are also part of the National Highway Freight Network. MD 2, MD 3, and US 50 have been identified as potential transit corridors.

SAFETY OVERVIEW: The highest concentrations of crashes are along MD 3 and MD 450. There are also high concentrations of crashes along I-97 around MD 100 and along US 50/US 301 between MD 2 and I-97 and at the MD 3 interchange. Crash data shows that the highest number of crashes occur during the AM or PM peak and the most common crash type is rear ends. In 2018, there were 1923 crashes reported within TSMO System # 3, with 18 fatalities and 785 injuries.

  - Annual O&M: $1.7 M
**TSMO MASTER PLAN**

**TSMO SYSTEM # 4**

**BACKGROUND:** TSMO system # 4 improves operations along US 50 and parallel local roads approaching the Bay Bridge Crossing. The rush to cross the Bay Bridge during the summer begins around 10 AM and extends through 7 PM, during which ~45,000 vehicles attempt to cross. When crashes occur ~25% of traffic attempts to bypass congestion by diverting to MD 18. US 50 is also designated Maryland Freight Route and is part of the National Highway Freight Network.

**SAFETY OVERVIEW:** The highest concentrations of crashes are along US 50/US 301 around MD 2 and on the east side of the Bay Bridge. Crash data shows that the highest number of crashes occur in the afternoon and the most common crash type is rear ends. In 2018, there were 245 crashes reported within TSMO System # 4, with zero fatalities and 92 injuries.

---

![Crash Density Map](image)

**Crash Density:** Sparse ➔ Dense

**Safety Overview:** The highest concentrations of crashes are along US 50/US 301 around MD 2 and on the east side of the Bay Bridge. Crash data shows that the highest number of crashes occur in the afternoon and the most common crash type is rear ends. In 2018, there were 245 crashes reported within TSMO System # 4, with zero fatalities and 92 injuries.

Annual recurring costs: $16.8 K
Annual O&M costs: $1.2 M

Sub-system Deployment:

System 4.4.1
(BC: 3)
Tier 3

US 50/US 301 Hard Shoulder Running (ITS)
Deployment of dynamic lane controls, fixed cameras, CCTV, Communication and ITS equipment, and fiber
connection for outside hard shoulder running along US 50/US 301 at key locations.
PE: $0.5 M
CD: $3.5 M
Recurring Cost: $572.1 K
Annual O&M: $0.5 M

System 4.4.2
(BC: 3)
Tier 3

US 50/US 301 Hard Shoulder Running (Roadway)
God improvements for outside hard shoulder running along
US 50/US 301 at key locations.
PE: $2.0 M
CD: $13.3 M

Progress Status:

- Detailed traffic operations analysis (completed)
- All Electronic Tolling (planned)
- Bay Bridge Crossing Study (underway)
BACKGROUND: TSMO System # 5 improves operations along MD 210 and surrounding local transportation network. MD 210 is a commuter route, with heavy congestion in the AM towards Washington DC and the reverse in the PM. The system is compatible with PG County’s proposed hard shoulder running and with the Selected Alternative from the NEPA study and the ongoing Kerby Hill interchange project.

SAFETY OVERVIEW: MD 210 suffers from higher than average crash rates related to speeding and aggressive driving. The highest concentrations of crashes are along MD 210 between MD 373 and MD 228. Crash data shows that the highest number of crashes occur outside the regular peak periods and the most common crash type is rear ends. In 2018, there were 218 crashes reported within TSMO System # 5, with zero fatalities and 106 injuries.

- Nice Bridge Project (funded - potential situational awareness improvements)
**TSMO MASTER PLAN**

**TSMO SYSTEM # 7**

**BACKGROUND:** System # 7 provides primary north-south access to Calvert County and connects to St. Mary’s County. It provides commuters access to Washington DC and the Patuxent Naval Air Station. St. Mary’s County’s largest employer, The Thomas Johnson bridge connects St. Mary’s and Calvert counties over the Patuxent River and serves as an evacuation route for the Calvert Cliffs Nuclear Power Station. High traffic volumes across the bridge during peak travel periods cause frequent delays.

**CRASH DENSITY**

The highest concentrations of crashes are along MD 235 between MD 4 and MD 237. MD 2/ MD 4 also has high concentration of crashes around Prince Frederick. Crash data shows that the highest number of crashes occur in the afternoon and the most common crash type is rear ends. In 2018, there were 617 crashes reported within TSMO System # 7, with one fatality and 288 injuries.

**SAFETY OVERVIEW:**

- Head On (8)
- Intersection (84)
- Rear End (237)
- Side Swipe (179)
- Angle (44)
- Single Vehicle (150)
- Other (35)

**TSMO MASTER PLAN**

**TSMO SYSTEM # 8**

System # 8 provides access to Ocean City, primarily during the summer season. US 50 is also envisioned as a future Freight Corridor. System improvements are compatible with the US 50 Ocean Gateway Study and MD 589 Feasibility Study recommendations.

**SYSTEM LIMITS:**

- **UNCONGESTED (TTI < 1.15)**
- **MODERATE CONGESTION (1.15 < TTI < 1.3)**
- **HEAVY CONGESTION (1.3 < TTI < 2.0)**
- **SEVERE CONGESTION (TTI > 2.0)**

**SAFETY OVERVIEW:**

- The highest concentrations of crashes are along US 50 between MD 610 and east of MD 90. Crash data shows that the highest number of crashes occur between 6:00 AM and 8:00 AM and between 1:00 PM and 5:00 PM when vacationers travel to or return from the beach and the most common crash type is rear end. In 2018, there were 295 crashes reported within TSMO System # 8, with one fatality and 140 injuries.

TSMO MASTERS PLAN

TSMO SYSTEM # 9

BACKGROUND: TSMO System # 9 improves operations along the I-95 corridor that connects Baltimore with Delaware. Within the system, I-95 has three parallel routes: US 1, MD 7, and US 40. I-95 and US 40 are designated as Maryland Freight Routes. I-95 is also designated as part of the National Highway Freight Network.

SAFETY OVERVIEW: The highest concentrations of crashes are along US 40 around Rossville Boulevard, and along I-95 between New Forge Road and the Baltimore County/ Harford County line. Crash data shows that the highest number of crashes occur during the PM peak and the most common crash type is rear ends. In 2018, there were 2317 crashes reported within TSMO System # 9, with 22 fatalities and 1043 injuries.

PROGRESS STATUS:

- I-95 Managed Lane System (MdTA)
- US 40 Hatem Bridge All Electronic Tolling (MdTA)
- Concept of Operations (TBD)
BACKGROUND: TSMO System # 10 improves operations along the north-south corridor connecting the City of Baltimore with northern locations up to the PA State Line. Traffic operations reflect the commuter pattern, with heavy congestion approaching I-695 in the morning and returning in the afternoon. I-83 is designated as a Maryland Freight Route and is part of the National Highway Freight Network. MD 45 has been identified as potential transit corridor.

SAFETY OVERVIEW: The highest concentrations of crashes are along I-83 around the interchange with MD 45 and south of MD 439. The highest concentration of crashes along MD 45 is near I-695, Timonium Road, Padonia Road, and between MD 145 and Shawan Road. Crash data shows that the highest number of crashes occurs during the PM peak and the most common crash type is rear ends. In 2018, there were 746 crashes reported within TSMO System # 10, with five fatalities and 201 injuries.

**TSMO MASTER PLAN**

**TSMO SYSTEM # 11**

BACKGROUND: TSMO System # 11 connects Baltimore with locations northwest, traversing Reisterstown and connecting to Westminster. Traffic operations follow commuter patterns, with heavy southbound traffic in the morning, and heavy northbound traffic in the afternoon. The system includes the Baltimore Light Rail that parallels I-795. I-795 is a Maryland Freight Corridor and part of the National Highway Freight Network. MD 140 has been identified as a potential transit corridor.

**SAFETY OVERVIEW:** The highest concentration of crashes along I-795 is at the interchange with Owings Mills Boulevard. The highest concentration of crashes along MD 140 is near I-695 and near MD 128. Crash data shows that the highest numbers of crashes occur during the AM and PM peak and the most common crash type is rear ends. In 2018, there were 665 crashes reported within TSMO System # 11, with one fatality and 339 injuries.

Cabinet, have Video Detection, have CAV Equipment, ATMS
Fiber connections for ITS deployment in sub-systems and to MD

- Concept of Operations (TBD)

Civil improvements for outside hard shoulder running along I-795 at key locations.

- Concept of Operations (TBD)
SAFETY OVERVIEW: The highest concentrations of crashes occur along I-270 at the interchange between Gaithersburg and Clarksburg and around the MD 85 interchange. Crash data shows that the highest numbers of crashes occur during the AM and PM peak and the most common crash type is rear ends. In 2018, there were 855 crashes reported within TSMO System #12, with three fatalities and 531 injuries.

BACKGROUND: TSMO System #12 connects Washington DC with the City of Frederick and locations north, connecting to US 15 and I-70. I-270 is currently being upgraded as part of the ICM project, and is part of the Governor’s Traffic Relief Plan, and will include ETIs in the future. I-270 is a Maryland Freight Route and is part of the National Highway Freight Network. The system runs parallel to the Red Line Metrorail. MD 355 has been identified as a potential transit corridor.

- I-270 TRP (ongoing)
BACKGROUND: TSMO System #13 provides critical connection between Washington DC and Baltimore and is part of the I-95 corridor. Parallel freeways and arterials include US 29, US 1, and MD 295. MD 295 is part of the Governor’s Traffic Relief Plan. I-95 is a Maryland Fright Route and is part of the National Highway Freight Network. US 29 and US 1 have been identified as potential transit corridors. Local plans include BRT on US 29.

SAFETY OVERVIEW: The highest concentrations of crashes occur along I-95 north and south of MD 175 (overall area with TSMO System 2), south of MD 32, and at the interchanges with MD 212 and I-495. US 1 also has a high concentration of crashes surrounding the interchange with I-495. Crash data shows that the highest numbers of crashes occur during the AM and PM peak and the most common crash type is rear ends. In 2018, there were 2,928 crashes reported within TSMO System #13, with 12 fatalities and 1,067 injuries.

**TSMO SYSTEM #14**

![Diagram of TSMO System #14 showing key highways and intersections like I-68, I-70, US 219, WV Line, West Virginia, etc., with crash density and safety overview information.]

**BACKGROUND:** TSMO System #14 is the critical east-west link supporting the Baltimore-Washington metropolitan region and supports import and export supply chains to and from the Part of Baltimore and Maryland markets. I-70 and I-68 are Maryland Freight Routes and part of the National Highway Freight Network. Key commodities in the region supported include mining, agriculture, and retail supporting over 24K businesses and 326K jobs. TSMO System #14 experiences illegal truck parking and congestion.

**VERTICAL CRASH DENSITY:**

</tbody>
</table>

**SAFETY OVERVIEW:** The highest concentrations of crashes occur along I-70 around Hagerstown and along the stretch of highway paralleling the Potomac River. I-68 has the highest concentration of crashes west of Hancock. Crash data shows that the highest number of crashes occur between 10:00 AM and 7:00 PM and the most common crash type is single vehicle crashes. In 2018, there were 486 crashes reported within TSMO System #14, with four fatalities and 215 injuries.

**TSMO MASTER PLAN**

**TSMO SYSTEM # 15**

**SAFE OVERVIEW:** The highest concentrations of crashes occur along I-81 north of MD 58 and between the PA line and Showers Road. Crash data shows that the highest number of crashes occur between 4:00 PM and 5:00 PM and the most common crash type is single vehicle crashes. In 2018, there were 160 crashes reported within TSMO System # 15, with zero fatalities and 59 injuries.

**BACKGROUND:** TSMO System # 15 is a critical truck thoroughfare and interstate crossroads linking northern and southern markets: the Baltimore-Washington area to northern U.S. and southern U.S. markets. I-81 is a Maryland Freight Corridor and is part of the National Highway Freight Network. The system also supports major railroad intermodal terminals, as well as one of Maryland’s critical cargo bearing airports. Major markets supported include energy (solar/biomass), construction, utilities, manufacturing, wholesale, retail, and healthcare.

BACKGROUND: TSMO System #16 provides alternate north-south freight route connecting US 301 with US 13, and provides access to the Eastern Shore and Washington DC. This is a key corridor connecting the Baltimore-Washington region to Eastern Shore markets and the Port of Virginia (Norfolk). The corridor is vital for poultry and agricultural production, supporting technology and defense industries, and other freight flows between regions and major port areas. US 50 and US 13 are Maryland Freight Routes and Critical Rural Freight Corridors.

SAFETY OVERVIEW: The highest concentrations of crashes occur along US 50 east of the split with US 301, around Easton and Vienna, and near the interchange with US 13. Crash data shows that the highest number of crashes occur between 10:00 AM and 6:00 PM and the most common crash type is single vehicle crashes. In 2018, there were 871 crashes reported within TSMO System #16, with seven fatalities and 572 injuries.

TSMO MASTER PLAN

TSMO SYSTEM # 17

TSMO SYSTEM # 17 provides alternative north-south freight route by connecting Delaware with US 50. This is a critical corridor for Maryland industries of agriculture, manufacturing, chemical production, and food/poultry production. This system provides a vital link between the Baltimore/Washington market and both northeastern U.S. and Eastern Shore markets. US 301 is a Maryland Freight Route and a Critical Rural Freight Corridor. Illegal truck parking is high on the corridor due to low availability.

BACKGROUND:

CRASH DENSITY:
The highest concentrations of crashes occur along US 301 east of the split with US 50 and near the intersection with MD 405. Crash data shows that the highest numbers of crashes occur between 10:00 AM and 12:00 PM and between 3:00 PM and 5:00 PM and the most common crash type is single vehicle crashes. In 2018, there were 117 crashes reported within TSMO System # 17, with two fatalities and 60 injuries.

US 301 ITS Deployment
Deployment of an In-Motion Weight Station, a Weather Station, VMS signs, CCTV, traffic detectors, and RSU along US 301 between US 50 and DE State Line.

System 17.2.1
(B/C: <1)
Tier 2
US 301 Traffic Signal Upgrade
Upgrade existing traffic signals along US 301 between US 50 and DE State Line to be fully-actuated, equipped with 5-Cabinets, and have Video Detection.

System 17.3.1
Tier 3
Telecommunications
Fiber connections for ITS deployment in sub systems and to provide critical connections for the network.

PROGRESS STATUS:
- Concept of Operations (TBD)

<tr>
<td>AW1,01</td>
<td>CCTV replacement (Phase I)</td>
<td>Replace all existing CCTV cameras at end of lifecycle with latest technology cameras to continue monitoring roadway conditions using the cutting-edge national communication protocol standards. Typically, CCTV cameras have a productive lifespan of approximately ten years due to exposure to extreme outdoor conditions, failures in P12 motor assemblies, deterioration of the anti-glare lens coating, and other image quality related issues. Additionally, spare part availability from manufacturers is not guaranteed.</td>
<td>$0.5</td>
<td>$120</td>
<td>$60</td>

<td></td>
</tr>
<tr>
<td>AW1,04</td>
<td>Portable Trailer Cameras</td>
<td>Portable trailer-mounted cameras provide the functionality of any other CCTV camera, but with the flexibility to be mobile. These cameras may be used for semi-permanent (construction situation) or temporary (incident and emergency management) applications.</td>
<td>$0.4</td>
<td>$9</td>
<td>$50</td>
</tr>
<tr>
<td>AW1,05</td>
<td>Deploy permanent traffic monitoring equipment at work zones</td>
<td>Additional traffic monitoring devices will benefit construction zones in detecting and monitoring incidents, hazardous conditions, and congestion. This will improve incident response to dispatch the correct equipment for faster and more efficient incident removal; it will improve safety by detecting hazardous conditions to facilitate alerting motorists; and it will reduce delay by detecting and monitoring congestion to facilitate management of traffic flow.</td>
<td>$2.3</td>
<td>$4</td>
<td>$290</td>
</tr>
<tr>
<td>AW1,06</td>
<td>Purchase portable trailer mounted traffic detectors</td>
<td>Purchase portable side-fire traffic detectors mounted on trailers, with wireless communications to provide flexible monitoring capabilities at any location in the state. These detectors provide the functionality of any other traffic detector, but with the flexibility of mobility. These detectors may be used for semi-permanent (construction situation) or temporary (incident and emergency management applications).</td>
<td>$0.6</td>
<td>$14</td>
<td>$80</td>
</tr>
<tr>
<td>AW1,07</td>
<td>Deploy enhanced HAR at existing sites</td>
<td>Replace the existing HAR systems with leading edge synchronized HAR technology to ensure superior service to broadcast live traveler information effectively. Synchronized HAR systems will be coordinated with MDTA to assure the messages and coverage areas are consistent among motorists traveling to/between MDOT SHA and MDTA-operated facilities.</td>
<td>$0.6</td>
<td>$6</td>
<td>$70</td>
</tr>
<tr>
<td>AW1,08</td>
<td>Replace portable DMS</td>
<td>Replace existing portable DMS trailers with the latest solar power technology and wireless communication medium.</td>
<td>$1.5</td>
<td>$24</td>
<td>$190</td>
</tr>
<tr>
<td>AW1,09</td>
<td>Roadside infrastructure for in-vehicle hazard alert</td>
<td>Install roadside detectors, and short-range radio transmitters and antennas to detect hazardous traveling conditions and alert traveling vehicles via radio. This infrastructure will provide motorists in-vehicle real-time information regarding immediate hazards and congestion in downstream lanes on highways, tailored to vehicles within the broadcast area. The service will reduce primary and secondary incidents and provide drivers the information to choose alternate routes at decision points prior to highway on-ramps.</td>
<td>$0.7</td>
<td>$5</td>
<td>$90</td>
</tr>
<tr>
<td>AW1,10</td>
<td>Replace roadside weather stations (Phase I)</td>
<td>Existing RWS sensors are maintenance intensive. This project retrofits/ upgrades the existing Roadside Weather Information Stations with Remote Processing Units (RPU) technology. Replacing existing weather stations provides reliable information regarding current weather conditions, which will be passed along to travelers using CHART’s website, DMS, HAR, and other available media. RPU technology will collect and transmit weather data to locations with existing traffic cabinets such as traffic signals or dynamic message signs.</td>
<td>$1.7</td>
<td>$18</td>
<td>$210</td>
</tr>
<tr>
<td>AW1,11</td>
<td>Replace roadside weather stations (Phase II)</td>
<td>$1.6</td>
<td>$18</td>
<td>$210</td>
<td></td>
</tr>
<tr>
<td>AW2,01</td>
<td>Install mile markers (Phase I)</td>
<td>Install mile marker signs at every 0.10 mile interval along all freeways and expressways within the state of Maryland. This improves CHART’s ability to locate and report incidents and hazardous conditions with greater precision for faster and more efficient incident removal to facilitate management of traffic flow.</td>
<td>$0.8</td>

<td>$290</td>
</tr>
<tr>
<td>P1.03</td>
<td>Incident management field equipment for Agencies</td>
<td>Provide and transfer equipment to Maryland State Police (MSP) and other public safety agencies to improve coordination and joint activities with CHART. This project will provide additional equipment to public safety agencies to more effectively respond, log, investigate, report, clear, and restore traffic operations to normal conditions during incidents and emergency evacuations.</td>
<td>$1.3</td>
<td>$20</td>
<td>$200</td>
</tr>
<tr>
<td>P1.04</td>
<td>Deploy AVL technology in CHART vehicles</td>
<td>Install AVL equipment on future CHART vehicles. AVL technology in incident/emergency vehicles will give dispatchers greater knowledge about locations of vehicles and enable the nearest vehicle to be dispatched to an incident. This will provide faster response times, resulting in fewer secondary incidents and less delay for travelers.</td>
<td>$0.03</td>
<td>$4</td>
<td>$5</td>
</tr>
<tr>
<td>P1.05</td>
<td>Replace portable data sharing devices for personnel</td>
<td>Replace existing in-vehicle laptops with hand-held field computers for field operators to report quality real-time information on incidents and emergency events wirelessly to CHART remote incident management personnel to facilitate incident/emergency management field operations. These devices help make the reporting process less time-consuming by recording data electronically in the field and transmitting the captured images wirelessly to CHART centers and other CHART system users via VPN/APN path.</td>
<td>$0.3</td>
<td>$43</td>
<td>$40</td>
</tr>
<tr>
<td>P1.06</td>
<td>Deploy Trail Blaze signage for FITM (Phase I)</td>
<td>Furnish and store portable trail blaze signage systems for approximately 100 Freeway Incident Traffic Management (FITM) routes. This project includes approximately 20 mobile trailers at strategic locations within the various districts to facilitate the storage and mobilization of temporary devices for special events and incident management. Deployment will increase information dissemination to motorists along FITM routes during special events and non-recurring incidents. This will more efficiently manage traffic during detour and evacuation situations, resulting in reduced delay and occurrences of secondary incidents.</td>

<tr>
<td>$1,01</td>
<td>Integrate CHART CCTV with other agencies</td>
<td>Integration to use video in the current standard format across existing network connections through the statewide government intranet. This project requires administrative configurations of new CCTVs in the system and will enable the exchange of video between CHART and other agencies. It also includes potential required modifications to the CHART video subsystem (if any) to support external agency CCTVs, which may include updates to Java, the operating system, etc. This will improve regional coordination between CHART Operations personnel and local traffic management operations personnel by providing local traffic management personnel access to CHART data and systems. This project will extend CHART and local CCTV coverage to previously unmonitored travel routes and will improve inter-agency response coordination, incident traffic management, and emergency/evacuation traffic management.</td>
<td>$0.5</td>
<td>N/A</td>
<td>$20</td>
</tr>
<tr>
<td>$1,02</td>
<td>Enhance for automatic incident/ congestion alerts (Phase I)</td>
<td>Enhance the CHART software to process Traffic Sensor Subsystem data for the system to automatically generate incident and congestion alerts. The traffic flow monitoring subsystem currently produces traffic flow information for both freeway and arterials, using data obtained from traffic detectors and traffic probe system inputs. The data received by the traffic flow monitoring subsystem comes from devices in CHART or data received from external sources (e.g., probe data). This enhancement to the Traffic Sensor Subsystem module will provide the capability to interpret the data feed to automatically generate incident and congestion alerts to the alert subsystem of the CHART system. Enhancement to the software to generate incident and congestion alerts will improve incident response time, incident traffic management, emergency traffic management, and traveler information.</td>

The MD 511 project also leverages HIBs with dynamic flashers. These devices will be used for detection and reduction of traffic backups on highways. The system will monitor and control devices as an enhancement to the TSS using defined business rules to control the flow of traffic and information provided to travelers based on the data collected from the TSS to optimize system throughput. This project allows CHART to directly alert motorists of upcoming congestion or hazardous traffic conditions on freeways/expressways before reaching the decision points at arterial and freeway/expressway intersections and on-ramps to decrease congestion levels on freeways/expressways.</td>
